

`sudo apt-get install git.`

When We are in a directory and we want to start working with GIT, the first command is

`$ git init` which means from now on this directory is under control of git.

- 1) make a file -> change the file -> bring it to "stage mode" -> commit it.

`$ git status`

```

MINGW64/g/GitRepositories

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories
$ touch newFile.html

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories
$ git status
fatal: not a git repository (or any of the parent directories): .git

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories
$ git init
Initialized empty Git repository in G:/GitRepositories/.git/

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories (master)
$ git status
On branch master

No commits yet
Untracked files:
  (use "git add <file>..." to include in what will be committed)
    newFile.html

nothing added to commit but untracked files present (use "git add" to track)

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories (master)
$ |
  
```

- 2) In order to make it staged, we say :

```
$ git add <file name>
```

```
$ git add . -> adds all files that are not already added or changed somehow.
```

```
$ git add -A -> adds all files that are not already added or changed somehow.
```

 MINGW64:/g/GitRepositories

```
Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories (master)
$ git add newFile.html

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories (master)
$ |
```

- 3) Let's Tell git who we are and who is going to make changes to the file.

```
$ git config --global user.email "<emailAddress>"
```

OR

```
$ git config --global user.name "<Your name>"
```

```
Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories (master)
$ git config --global user.email "Hossein.dehghanipour1998@gmail.com"
```

- 4) when we make a change, git calls it an "Untracked File|change".

```
$ git commit -m "*"
```

instead of the "*", we write some descriptions of what we have done (the changes) to the files.

```
Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories (master)
$ git commit -m "Added Changes to the newFile.html"
[master (root-commit) d01ff3a] Added Changes to the newFile.html
1 file changed, 6 insertions(+)
create mode 100644 newFile.html
```

- 5) **\$ git log** tells us what ever we have done to this git repository and who has made what changes.

```
Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories (master)
$ git log
commit a71810ed174106f8931b8b43cc082bd1cc826d91 (HEAD -> master)
Author: Hossein Dehghanipour <Hossein.dehghanipour1998@gmail.com>
Date: Fri Aug 30 21:00:09 2019 +0430

    Made new Changes to the files

commit d01ff3a58f33d54d0db42929d684485e337a3176
Author: Hossein Dehghanipour <Hossein.dehghanipour1998@gmail.com>
Date: Fri Aug 30 20:54:03 2019 +0430

    Added Changes to the newFile.html

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories (master)
$ |
```

Head is where we are **right now** which is usually the last repository we are working on.

- 6) when we make some files at the “Staged” position but we are not sure if we have made the correct changes. so we use **\$ git diff --staged** to see the changes made to the files.

```

Branching & Merging :

Assume that we are working on a project and each member of the team has taken responsibility for a different part of the project. One is taking control over “Security”, one is creating the “UI” and another guy is going to create the part of our application that asks for “CAPTCHA”. So if we assume that the red line is our **Master** branch (Main branch), guy #1 is going to work on the CAPTCHA by making his own branch and guy #2 is also going to work on the security simultaneously and they all **Merge** after they have done their job. The key point in here is that they are doing different things and there might not be an overlap in their tasks.

`$ git branch` -> Shows our current branch that we are in

`$ git branch <branch name>`

you should have a commit on the master in order to create a new branch.

```

MINGW64:/g/GitRepositories/Testing Repository

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (master)
$ git branch
* master
  
```

Our current branch

```

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (master)
$ git branch fixNames
  
```

we have created a new branch named "fixNames"

```

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (master)
$ git checkout fixNames
Switched to branch 'fixNames'
  
```

we switched from current branch to another branch

```

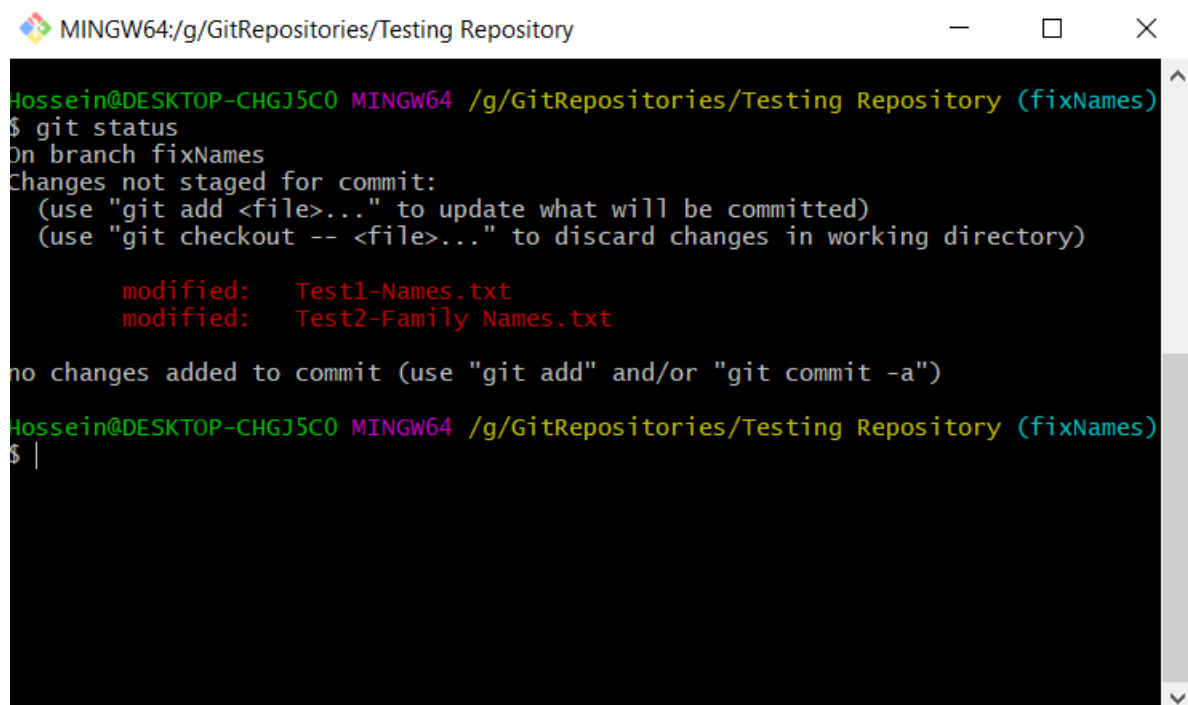

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (fixNames)
$ git branch
* fixNames
  master
  
```

now our current branch is fixNames after we switched

```

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (fixNames)
$
  
```

now if I add/change some files and then get the status that's what I will see :

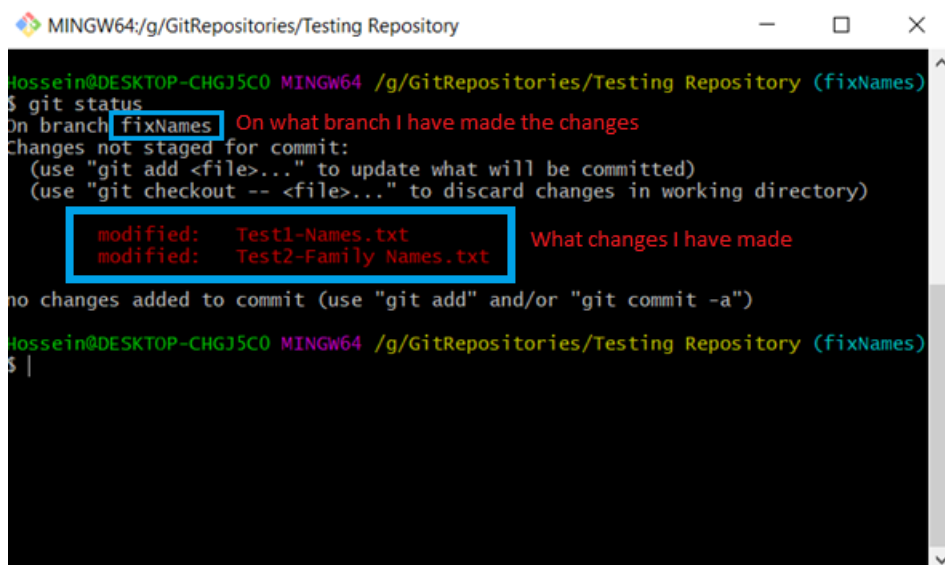

```

MINGW64:/g/GitRepositories/Testing Repository

some times we make changes to multiple files but they are not in the same category. We make separate commits for different categories. so we may have already added all files. What we must do is that we “reset” the unwanted files in the current commit and then we add them to another commit.

MINGW64:/g/GitRepositories/Testing Repository

```
Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (fixNames)
$ git status
On branch fixNames
Changes not staged for commit:
  (use "git add <file>..." to update what will be committed)
  (use "git checkout -- <file>..." to discard changes in working directory)
```

```
    modified:   Test1-Names.txt
    modified:   Test2-Family Names.txt
```

no changes added to commit (use "git add" and/or "git commit -a")

```
Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (fixNames)
$ git add .
```

```
Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (fixNames)
$ git reset Test1-Names.txt
Unstaged changes after reset:
M    Test1-Names.txt
```

that's where we have changed our mind

```
Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (fixNames)
$ git status
On branch fixNames
Changes to be committed:
  (use "git reset HEAD <file>..." to unstage)
```

```
    modified:   Test2-Family Names.txt
```

```
Changes not staged for commit:
  (use "git add <file>..." to update what will be committed)
  (use "git checkout -- <file>..." to discard changes in working directory)
```

```
    modified:   Test1-Names.txt
```

```
Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (fixNames)
$ git commit -m "Fixed Test2-FamilyNames.txt"
[fixNames b0ad86f] Fixed Test2-FamilyNames.txt
1 file changed, 3 insertions(+), 1 deletion(-)
```

```
Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (fixNames)
$ git status
On branch fixNames
Changes not staged for commit:
  (use "git add <file>..." to update what will be committed)
  (use "git checkout -- <file>..." to discard changes in working directory)
```

```
    modified:   Test1-Names.txt
```

no changes added to commit (use "git add" and/or "git commit -a")

```
Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (fixNames)
$ git add .
```

```
Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (fixNames)
$ git commit -m "Fixed Test1-Names file"
[fixNames b631e2d] Fixed Test1-Names file
1 file changed, 2 insertions(+), 1 deletion(-)
```

```
Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (fixNames)
$ git commit -m "Fixed Test1-Names file"

1 file changed, 2 insertions(+), 1 deletion(-)

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (fixNames)
$
```

Now assume that we switch to our master branch. as we know we have made some changes in our other branch "fixNames". In order to have the changes on our master branch too, we have to merge them :

```
Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (fixNames)
$ git checkout master
Switched to branch 'master'

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (master)
$ git status
On branch master
nothing to commit, working tree clean

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (master)
$ git branch
  fixNames
* master

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (master)
$ git merge fixNames
Updating a01bf88..b631e2d
Fast-forward
 Test1-Names.txt      | 7 +++++-
 Test2-Family Names.txt | 5 +++++
 2 files changed, 11 insertions(+), 1 deletion(-)

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (master)
$
```

```
Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (master)
$ git log

    Made Changes to Names and FamilyNames

commit a01bf88913f2639780e3d2003c13b0fe4e8cc27e
Author: Hossein Dehghanipour <Hossein.dehghanipour1998@gmail.com>
Date:   Mon Sep 9 19:15:17 2019 +0430

    Added test files

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (master)
$
```

If we want to delete a file from git, we write `$ git rm <file name>` this command deletes the following file from both git and file system.

I can also use `LS` command in order to see the files in my branch.

```
Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (master)
$ ls
'My Master Address.txt'  Test1-Names.txt  'Test2-Family Names.txt'

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (master)
$ git rm Test1-Names.txt
rm 'Test1-Names.txt'

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (master)
$ ls
'My Master Address.txt'  'Test2-Family Names.txt'

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (master)
$ git status
On branch master
Changes to be committed:
  (use "git reset HEAD <file>..." to unstage)

        deleted:    Test1-Names.txt

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (master)
$
```

after we have done with our branch and we have merged it, we can delete the branch. so we use the command `$ git branch -d <branch name>`.

```
Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (master)
$ git branch
  fixNames
* master

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (master)
$ git branch -d fixNames
Deleted branch fixNames (was b631e2d).

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (master)
$ git branch
* master

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (master)
$ |
```

but it doesn't show us that we have deleted a branch :

```
Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (master)
$ git branch
  fixNames
* master

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Repository (master)
$ git branch -d fixNames
Deleted branch fixNames (was b631e2d).

Use Git or checkout with SVN using the web URL.

<https://github.com/hosseindehghanipour1998/micro-homeworks>

Open in Desktop Download ZIP

\$ git clone <the address copied from git >

\$ git push origin master

when we clone a project from github, the remote set to the master of the project is usually “origin”.

\$ git pull origin master

if we have a public repository, we can pull from it but pushing to a repository requires the owner’s permission.

we can add a remote to our directory. we can make remote to any directory from any other directory. If the directory doesn’t exist, we will face an error that tells us the path/URL we are aiming for doesn’t exist as a GIT repository.

our projects can have more than one remotes. We can push our project onto two different servers or pull from two different servers. for example, as a new commit is made we can push it to both gitlab and github simultaneously with two different remotes pointing to different servers.

\$ git remote add <URL> -> creates a new remote to the project

\$ git remote -v -> shows us all the available remotes in the project.

```
Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Clone/micro-homeworks
(master)
$ git remote -v
origin https://github.com/hosseindehghanipour1998/micro-homeworks.git (fetch)
origin https://github.com/hosseindehghanipour1998/micro-homeworks.git (push)

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Clone/micro-homeworks
(master)
$ git remote add cRemote https://github.com/hosseindehghanipour1998/principles-o
f-programming-2019.git

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Clone/micro-homeworks

$ git remote -v
cRemote https://github.com/hosseindehghanipour1998/principles-of-programming-2019.git (fetch)
cRemote https://github.com/hosseindehghanipour1998/principles-of-programming-2019.git (push)
origin https://github.com/hosseindehghanipour1998/micro-homeworks.git (fetch)
origin https://github.com/hosseindehghanipour1998/micro-homeworks.git (push)

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Clone/micro-homeworks (master)
$
```

In the illustration above we have created another remote to another repository of github named “ Principles-of-programming-2019 “ on which we can push and from which we can pull.

we can insert the copied URL into the terminal by pushing “ **ctrl + insert** “

some times we have a major problem. This problem will be caused when two different users are making changes on one same file. They both commit on one exactly the same branch. When one of them is going to push on the branch his own changes he will face an error saying that “ error: failed to push to URL ... “.In these situations you have to pull first in order to have his changes and then push

your own changes on the branch. The git would automatically merge your changes as you pull the project but something worse might happen which is both of the programmers have changed same lines of code which is the base of a major conflict in the file. git status will tell you that you both of you have made modified changes. You have to handle it manually by yourself. If you open the file you will see such a thing :

```

3. vi README.md (vim)
پات<200c>یت زان
=====
<<<<<< HEAD
newline
=====
I
>>>>>> 47aa741e1c9b612cb8b20a8d28953ab713f0646a
یم یچک .نتفرگ دای اجنیا زا ور سکونیک ییادتیا تاروتسد هک ییاد<200c>هچب نیرمت یارب دیال دنماک یزای کب
.پات یت هب ندیسر یارب تاروتسد اب راک هب نیک یم غورث و موه یوت مینک
[http://linuxbook.ir/chapters/common_shell_commands.html]نتسد اجنیا تاروتسد یلدا تشرهف
.دینوخب ور README.txt لیاف غورث یارب
~
~
~

```

from the “<<<<<HEAD” till “=====” are the changes you have made and the line under the “=====” are the changes the other guy has made to this file.

and the line “>>>>>>>>47.... “ is the name(hash) of the commit.

You can currently change and edit the file in order to solve the conflict and then make a new commit in order to push on the branch.

by **\$ git log** you can see that you have resolved the conflict.

But if the both programmers change different parts of the code or file , the git will merge them together and doesn't involve you to fix it manually.

by entering “git log” command you can see all the commits and their committers. but what else you can see is that it shows you the hash of the commits. by command **\$ git show <commit hash>** you can see the details of that commit .

```

Changes

After our project has reached a level that it's suitable for usage for the client, we public a version of our application. Or when we update or improve the app we upgrade it's version. As an example we call it "V 1.1.2". We call this operation tagging which means that we tag a label to our commit in order to remind ourselves that this commit is the first version of our program we have released and in the possible future when we want to look for our first released version we search for the tag instead of reading all changes and the codes we have written.

```
Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Clone/micro-homeworks (master)
$ git tag

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Clone/micro-homeworks (master)
$ git tag -a v2.0 -m "Our first version"

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Clone/micro-homeworks (master)
$ git tag
v2.0

Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Clone/micro-homeworks (master)
$ |
```

notice that **-a** stands for **annotation** and **-m** stands for **Message**.

assume that we are at the stage of v2.0 but we have forgotten to label our v1.8 . it's not late at all. all we have to do is to find the commit that makes out v1.8 and copy first 10-11 alphabets of it's hash. and then stick the wanted label to it.

```

now we have made tags but they are locally made. We have to also push the tags on our origin branch.

we say : `$ git push origin --tags` which pushes the tags on the main project on the server.

I can move to version v1.8 from where I am standing right now.

`$ git checkout <version name>` ex : `$ git checkout v1.8`

we are now standing on branch v1.8 but we can't make changes to this version and then commit it here. what we can do is make another branch on this version and make the changes on that branch then merge it with master.

The hash we see as commit is something beyond a simple string. That's a security procedure in order to avoid someone else making changes to the project in your name. So if it says that the commit is made by Hossein, That's definitely true. If someone wants to change the project and make it looks like you have done it, then he has to steal all of your keys and uses them against you which is a hard work and somehow impossible to do. The encryption that is used nowadays in computers is **PGP** which stands for **Pretty Good Privacy**.

GPG is the encryption for **Genau** Systems.(Google it)

In this system, There are a pair of keys for each user (we assume A & B). We keep A key to ourselves in order to encrypt what ever we write (we use it so make a digital Signature) and we publish key B for everyone to be able to see what changes we have made. So if someone can read some data with Key B it means that we had the Key A to encrypt it.

Ex : Assume there are 3 programmers. programmer A, B, C. Each one of these guys has two keys (A1, A2, B1, B2, C1, C2) each user encrypts his own data ba key #1 and publishes key #2 for others to use. If programmer B uses key A2 to read some data it means that is written by Programmer A only because only his key (A2) could decrypt the data.

Git works like this. Every user uses a key to encrypt and publishes the other key for others to decrypt the written data.

\$ `gpg --list-keys` -> this command shows you all of your keys.

let's make some keys :

\$ `gpg --gen-key`

```
Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Clone/micro-homeworks (master)
$ gpg --gen-key
gpg (GnuPG) 1.4.22; Copyright (C) 2015 Free Software Foundation, Inc.
This is free software: you are free to change and redistribute it.
There is NO WARRANTY, to the extent permitted by law.

gpg: keyring '/c/Users/hosse/.gnupg/secring.gpg' created
Please select what kind of key you want:
  (1) RSA and RSA (default)
  (2) DSA and Elgamal
  (3) DSA (sign only)
  (4) RSA (sign only)
Your selection? 3
DSA keys may be between 1024 and 3072 bits long.
What keysizes do you want? (2048) 1024
Requested keysizes is 1024 bits
Please specify how long the key should be valid.
  0 = key does not expire
  <n> = key expires in n days
  <n>w = key expires in n weeks
  <n>m = key expires in n months
  <n>y = key expires in n years
Key is valid for? (0) 1
Key expires at Wed, Sep 11, 2019  6:54:22 PM IDT
Is this correct? (y/N) y

You need a user ID to identify your key; the software constructs the user ID
from the Real Name, Comment and Email Address in this form:
"Heinrich Heine (Der Dichter) <heinrichh@duesseldorf.de>"

Real name: hossein
Email address: hossein.dehghanipour1998@gmail.com
Comment: Testing On making a Key
You selected this USER-ID:
"hossein (Testing On making a Key) <hossein.dehghanipour1998@gmail.com>"

Change (N)ame, (C)omment, (E)mail or (O)kay/(Q)uit? o
You need a Passphrase to protect your secret key.

We need to generate a lot of random bytes. It is a good idea to perform
some other action (type on the keyboard, move the mouse, utilize the
disks) during the prime generation; this gives the random number
generator a better chance to gain enough entropy.
+++++
gpg: key D2EA8FBC marked as ultimately trusted
public and secret key created and signed.

gpg: checking the trustdb
gpg: 3 marginal(s) needed, 1 complete(s) needed, PGP trust model

uid          hossein (Testing On making a Key) <hossein.dehghanipour1998@gmail.com>

Note that this key cannot be used for encryption. You may want to use
the command "--edit-key" to generate a subkey for this purpose.
```

the blue parts are the parts that get information from the user in order to create the key and the red part is the generated public key.

\$ git config --global user.signinkey this command tells us that with what key we have signed in.

\$git --list-secret-keys --keyid-format LONG

By the commands below we tell git to change our sign in key to what we give it (actually what we give must be a valid gpg key that we have already made) :

```
→ bestoon git:(master) git config --global user.name
jadi
→ bestoon git:(master) git config --global user.signingkey
BFC17529C96C4DFE
→ bestoon git:(master) gpg --list-secret-keys --keyid-format LONG
/Users/jadi/.gnupg/pubring.kbx
-----
sec   rsa2048/300B2487BB55DC4E 2018-06-05 [SC] [expires: 2020-06-04]
      D9C8249D50FAD6D4597A7543300B2487BB55DC4E
uid           [ultimate] jadi mirmirani <jadijadi@gmail.com>
ssb   rsa2048/F04093D09770674F 2018-06-05 [E] [expires: 2020-06-04]

→ bestoon git:(master) git config --global user.signingkey 300B2487BB55DC4E
→ bestoon git:(master)
```

as we have already said we can label our commits but if we write **-s** instead of **-a** it means **Sign** (not **annotate**) and after this command git requires a password from us in order to make sure that we are the real us :) and by typing :

\$ git show v2.1 then it shows who has released it and shows his digital signature key.

because some times some problems might be caused, either all members of the team should sign or none of the members should sign. Be aware that if you want to sign then you should sign all of the commits you make.

`$ git help <what?> -> $ git help blame`

`$ git blame <fileName> -L <Line Number >`

checks the specific line in that file in order to find who has done any changes on it.

`$git blame <File Name >`

checks the whole file and changes .

```
Hossein@DESKTOP-CHGJ5C0 MINGW64 /g/GitRepositories/Testing Clone/micro-homeworks

```

this allows us to blame the programmer who wrote the line of code which has a bug.

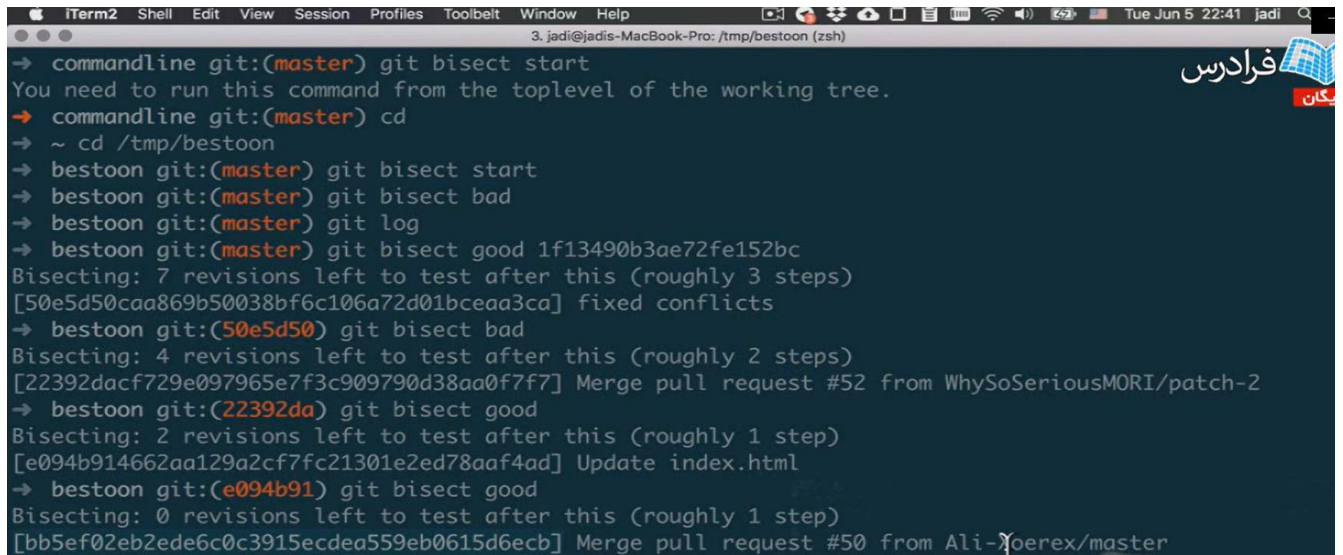

git has a tool which helps us find a bug due to our commits. you tell git to start your work in finding the bug :

`$ git bisect start`

ok. now we have started and we must be at the top directory level to call this command. we can say at each step whether the current commit is **good** or **bad**.

what git does is that is runs a binary search algorithm according to your saying about a commit to be good or bad and at each step git gives you the hash of a specific commit to check. If you **check** the code in that commit and see that the

code is fine you say `$ git insect good` otherwise you say `$git insect bad`.

```

→ commandline git:(master) git bisect start
You need to run this command from the toplevel of the working tree.
→ commandline git:(master) cd
→ ~ cd /tmp/bestoon
→ bestoon git:(master) git bisect start
→ bestoon git:(master) git bisect bad
→ bestoon git:(master) git log
→ bestoon git:(master) git bisect good 1f13490b3ae72fe152bc
Bisecting: 7 revisions left to test after this (roughly 3 steps)
[50e5d50caa869b50038bf6c106a72d01bceaa3ca] fixed conflicts
→ bestoon git:(50e5d50) git bisect bad
Bisecting: 4 revisions left to test after this (roughly 2 steps)
[22392dacf729e097965e7f3c909790d38aa0f7f7] Merge pull request #52 from WhySoSeriousMORI/patch-2
→ bestoon git:(22392da) git bisect good
Bisecting: 2 revisions left to test after this (roughly 1 step)
[e094b914662aa129a2cf7fc21301e2ed78aaf4ad] Update index.html
→ bestoon git:(e094b91) git bisect good
Bisecting: 0 revisions left to test after this (roughly 1 step)
[bb5ef02eb2ede6c0c3915ecdea559eb0615d6ecb] Merge pull request #50 from Ali-Xoerex/master

```

Forking :

we can fork a project from some other guy. We make some changes. Then we make a “pull request” in order to have the changes on that other guy’s project. so that guy should approve whether he wants you to make changes to his project or not.

- `git init`

شروع کار با git

- `git add fileName`

افزودن فایل به git

- `git add -A`

اضافه کردن همه فایل‌ها به git

- `git commit -m "description"`

کامیت کردن تغییرات با توضیحات

- `git status`

نمایش وضعیت

- `git reset fileName`

خارج کردن فایل از حالت stage

- `git diff HEAD`

نمایش وضعیت فعلی نسبت به وضعیت آخرین کامیت

- `git diff --staged`

نمایش وضعیت فعلی نسبت به وضعیت stage

- `git checkout --fileName`

فایل را از آخرین کامیت استخراج کرده و جایگزین فایل فعلی می‌کند

- `git branch`

نمایش شاخه‌های موجود

- `git branch branchName`

ساخت شاخه جدید با نام تعیین شده

- `git checkout branchName`

سوئیچ کردن از شاخه فعلی به شاخه تعیین شده

- `git merge branchName`

شاخه مذکور را با شاخه فعلی ادغام می کند

- `git rm fileName`

حذف فایل از git و از فایل سیستم

- `git branch -d branchName`

حذف شاخه

- `git push origin master`

شاخه master را به origin ارسال می کند

- `git pull origin master`

شاخه master را از origin دریافت می کند

- `git remote`

نمایش remote

- `git remote add origin url`

افزودن remote با آدرس تعیین شده و نام origin

- `git show commitID`

نمایش جزئیات commit با شناسه تعیین شده

- `git tag`

نمایش تگ ها

- `git tag -a tagName -m "description"`

افزودن تگ با نام و توضیحات تعیین شده

- `git show tagName`

نمایش جزئیات تگ

- `git blame fileName -L lineNumber`

مشاهده اینکه خط مذکور از فایل تعیین شده را چه کسی نوشته است

- `git bisect`

برای debug به کار می رود

- `git config`

برای تنظیمات ابزار به کار می رود. مانند مشخصات نویسنده و همچنین تنظیمات مربوط به پراکسی برای کلاینت گیت

Thanks to Jadi for this amazing tutorial.
